TDT4265: COMPUTER VISION

Assignment 1

Anders Kjelsrud

Task!

a) Have the binary cross entropy loss

$$C(\omega): \frac{1}{N} \sum_{i=1}^{N} C^{n}, \text{ where}$$

$$C^{n} = C^{n}(\omega) = -(y^{n} \ln(\hat{g}^{n}) + (1 - y^{n}) \ln(1 - \hat{g}^{n}))$$

where \hat{g} is the output and y is the ground broth want $\frac{\partial C^{n}(\omega)}{\partial w_{i}}$, the gradient of the cost function using the chain rule,
$$\frac{\partial C^{n}(\omega)}{\partial w_{i}} = \frac{\partial C^{n}(\omega)}{\partial y_{i}} \cdot \frac{\partial \hat{g}_{i}}{\partial z_{i}} \cdot \frac{\partial Z_{i}}{\partial w_{i}}$$
or with vector notetion:
$$\frac{\partial C}{\partial w_{i}} = \frac{\partial C(w)}{\partial \hat{g}_{i}} \cdot \frac{\partial \hat{g}_{i}}{\partial z_{i}} \cdot \frac{\partial Z_{i}}{\partial w_{i}}$$

$$\frac{\partial \zeta}{\partial \hat{S}} = -\left(\frac{9}{\hat{S}} - \frac{1-9}{1-\hat{S}}\right) = \frac{\hat{y}-y}{\hat{y}(1-\hat{y})}$$

and the hint
$$\frac{\partial f}{\partial w} = x$$
; $f(x)(1-f(x^n))$

we can combine the last two terms from the chain rule, namely that

$$\frac{\partial f(x^{2})}{\partial w_{i}} = 0 \cdot \lambda = \frac{\partial \hat{y}_{i}}{\partial z_{i}} \cdot \frac{\partial z_{i}}{\partial w_{i}}$$

$$= \times \hat{g} \left(1 - \hat{g} \right)$$

Combining all 3 terms gives

$$\frac{\partial c}{\partial w} = \frac{\hat{y} - y}{\hat{y}(1 - \hat{y})} \cdot \times \hat{y}(1 - \hat{y})$$

$$= \times (\hat{g} - g) = - \times (g - \hat{g}).$$

$$\Rightarrow \frac{\partial c^{n}(\omega)}{\partial \omega_{i}} = -(y^{n} - \hat{y}^{n}) \times_{i}^{n}$$

b) Have the softmax activation function

and the cross-entropy loss for multiple elasses $C(w) = \frac{1}{N} \sum_{i=1}^{N} C^{n}(w)$, $C^{n}(w) = -\sum_{i=1}^{N} y_{i}^{n} \ln(\hat{y}_{i}^{n})$

$$\frac{1}{1} \int_{\mathcal{K}} \int_$$

Want $\frac{\partial C^{n}(w)}{\partial w_{kj}} = \frac{\partial C^{n}}{\partial z_{k}} \frac{\partial z_{k}}{\partial w_{kj}}$ Start with $\frac{\partial}{\partial z_{j}} \frac{\partial C^{n}}{\partial z_{k}} \frac{\partial z_{k}}{\partial z_{j}} = \frac{\partial^{2} c^{2}}{\sum_{i=0}^{2} c^{2}}$

Use quotient rule; for $f(x) = \frac{g(x)}{h(x)}$ $f'(x) = \frac{g'(x) h(x) - h'(x) g(x)}{h(x)^2}$

choose $g(x) = e^{2x}$ and $h(x) = \frac{K}{1} e^{2x}$

Two cases:

$$\frac{if \quad k=j:}{\partial z_{j}} = \frac{z_{k}}{\sum_{k=1}^{k} e^{z_{k}}} = \frac{z_{k}}{\sum_{k=1}^{k} e^{z_{k}}} = \frac{z_{j}}{\sum_{k=1}^{k} e^{z_{k}}} = \frac{z_{k}}{\sum_{k=1}^{k} e^{z_{k}}} = \frac{z_{k}}{\sum_{k$$

$$\Rightarrow \frac{\partial \hat{y}_{k}}{\partial z_{j}} = \begin{cases} \hat{y}_{k}(1-\hat{y}_{j}) & \text{for } k=j\\ -\hat{y}_{j} & \hat{y}_{k} & \text{for } k\neq j \end{cases}$$

Now for the multiclass cross-entropy 1035:

$$c^{n}(\omega) = -\sum_{i}^{k} y_{k}^{n} \ln(\hat{y}_{k}^{n})$$

Lookatone case of n:

$$\Rightarrow \frac{\partial C}{\partial z} = \frac{\partial C}{\partial \hat{y}_{\kappa}} \frac{\partial \hat{y}_{\kappa}}{\partial z_{\kappa}}$$

$$= -\sum_{k=1}^{K} y_k \frac{\partial}{\partial z} \ln \left(\hat{y}_k \right) = -\sum_{k=1}^{K} y_k \frac{\partial}{\partial \hat{y}} \log \left(\hat{y}_k \right) \cdot \frac{\partial \hat{y}_k}{\partial z_j}$$

$$= - \frac{k}{2} \quad y_{k} \quad \frac{1}{\hat{y}_{k}} \quad \frac{\partial \hat{y}_{k}}{\partial z_{i}}$$

Using the result of softmax derivative:

$$\frac{\partial C}{\partial z_{\kappa}} = -y_{\kappa} \left(1 - \hat{y}_{\kappa} \right) - \sum_{i \neq \kappa} y_{i} \frac{1}{\hat{y}_{i}} \left(-\hat{y}_{i} \cdot \hat{y}_{\kappa} \right)$$

$$=-y_{K}+y_{K}\hat{y}_{K}+\sum_{i\neq 1}^{K}y_{i}\hat{y}_{K}$$

$$= \hat{y}_{k} \left(y_{k} + \sum_{i\neq 1}^{K} y_{i} \right) - y_{k}$$

using that $\sum_{i}^{K} y_{i} = 1$ and $y_{k} + \sum_{i\neq 1}^{K} y_{i} = 1$

$$\Rightarrow \frac{\partial C}{\partial Z_{K}} = \hat{y}_{K} - y_{K}$$

To get $\frac{\partial C}{\partial w_{kj}} = \frac{\partial C}{\partial Z_{K}} = \frac{\partial Z_{K}}{\partial w_{j}} = \frac{(\hat{y}_{k} - y_{k})}{(\hat{y}_{k} - \hat{y}_{k})} \times \frac{\partial Z}{\partial w} = x$

$$= -x_{j} \left(y_{k} - \hat{y}_{k} \right)$$

or for each dedecemble n

$$\frac{\partial C^{n}(w)}{\partial w_{kj}} = -x_{j}^{n} \left(y_{k}^{n} - \hat{y}_{k}^{n} \right)$$

1 Task 2

b) Training and validation loss over training is shown in Figure 1.

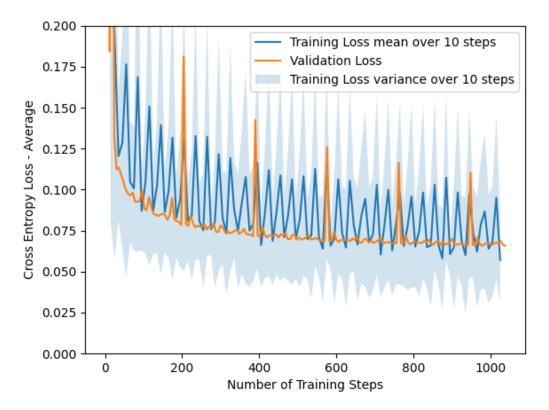

Figure 1: Loss

c) Accuracy is shown in Figure 2.

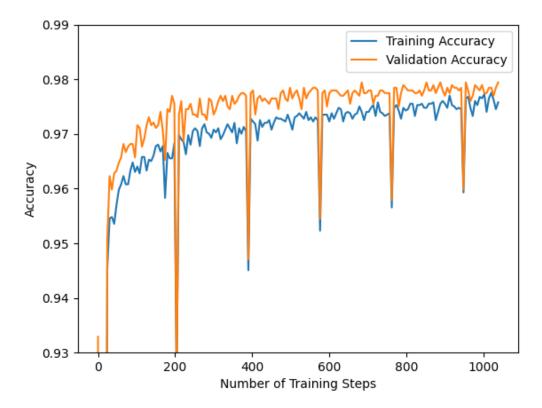

Figure 2: Accuracy

- d) Early stopping kicks in after 33 epochs.
- e) It happens because shuffling makes it less likely that the validation set will contain only examples from the same class. Thus the model's performance on the validation set will be more representative of how it would perform on new data. The opposite would be overfitting to the validation set. The difference in validation accuracy is shown in Figure 3. It is observed that early stopping kicks in way earlier.

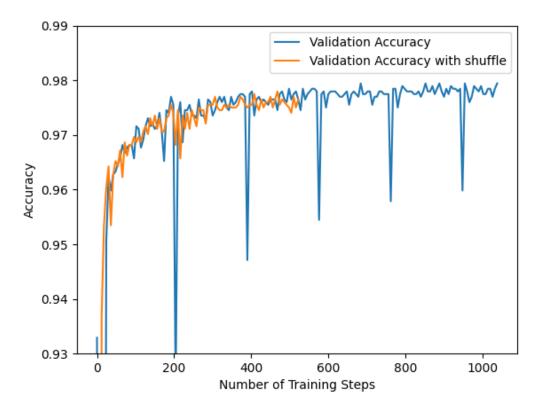

Figure 3: Shuffling

2 Task 3

b) Figure 4 shows the training and validation loss for Softmax.

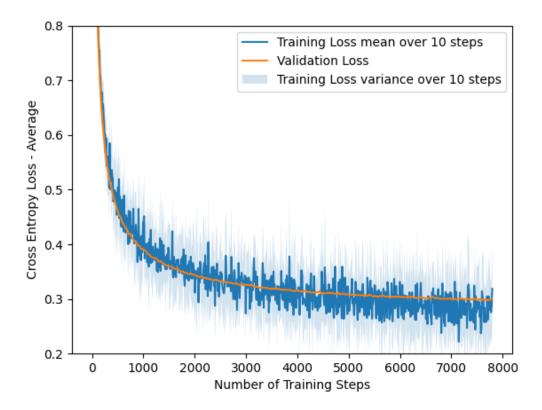

Figure 4: Softmax loss

c) Figure 5 shows the multi-class classification accuracy.

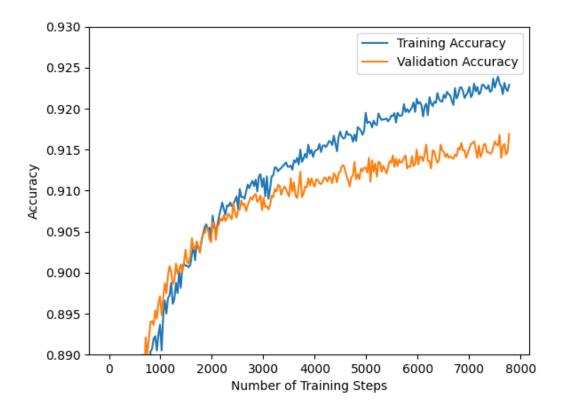

Figure 5: Softmax accuracy

d) There are signs of overfitting, namely that the accuracy is much higher on the training set than it is on the validation set. This is a sign that the model is unable to generalize well to new data.

3 Task 4

a)

Task H

Have that
$$\frac{\partial C^{n}(w)}{\partial w_{kj}} = -x_{j}^{n}(y_{k}^{n} - \hat{y}_{k}^{n})$$

Want $\frac{\partial J(w)}{\partial w}$ where $J(w) = C(w) + 72R(w)$

with $L2-reg: R = \frac{1}{2}\sum_{i,j}w_{i,j}^{n}$

$$= 3 \left(\omega \right) = \left(\left(\omega \right) + \pi + \pi + \frac{1}{2} \sum_{i,j} w_{ij}^{2} \right)$$

$$\Rightarrow \frac{\partial \mathcal{F}}{\partial \omega} = -\chi_{i} \left(y_{k} - \hat{y}_{k} \right) + \chi_{i} \kappa$$

b) The model with regularization has less noisy weights because the regularization term penalizes large weights and therefore the model is encouraged to find weights that are smaller in magnitude which could mean that the weights are less noisy. This is because smaller weights tend to produce less change in the model's output for a given input, which can make the model's predictions more stable and less sensitive to small variations in the input. Figure 6 shows the weights for two models with different λ -values. The first has $\lambda=0$ (no penalty), the second has $\lambda=2$.

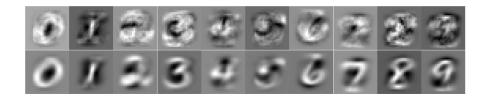

Figure 6: Model weights

c) Validation accuracy for different λ is shown in Figure 7.

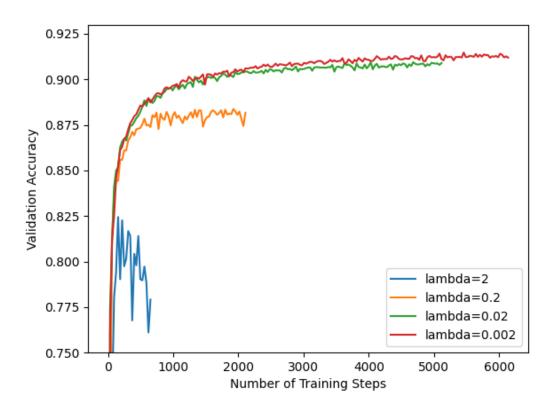

Figure 7: Accuracy for different λ

- d) Because a single layer NN is already quite simple and probably not able to generalize very well, adding a further restriction will make it even harder. A model this simple needs all the wiggle room it can get in terms of finding good weights to be able to learn a good representation of the data, therefore adding large regularization will in this case be too restrictive.
- e) We can see that the magnitude of the weights decrease as the regularization term increases.

This makes sense, because regularization is supposed to reduce model complexity by penalizing large weights. The magnitude of the weights are shown in Figure 8.

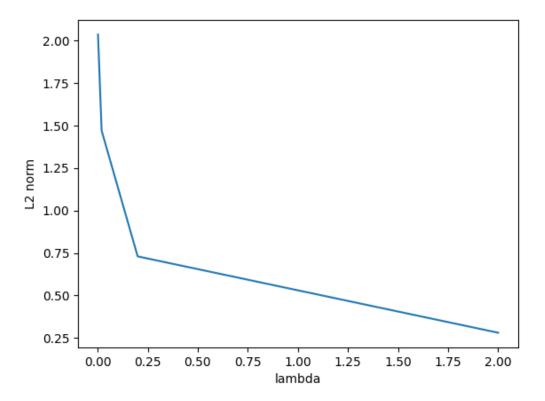

Figure 8: $||w||^2$
